Matches some or all of a string, based on the user-defined starting and ending index values within the string.

- Input must be a string literal value.
- Since the `SUBSTRING` function matches based on fixed numeric values, changes to the length or structure of a data field can cause your recipe to fail to properly execute.
- The `SUBSTRING` function requires numerical values for the starting and ending values. If you need to match strings using patterns, you should use the `extract` transform instead. See *Extract Transform*.

Basic Usage

```
derive type:single value:SUBSTRING('Hello, World',0,5)
```

Output: The string `Hello` is written to the new column.

Syntax and Arguments

```
derive type:single value:SUBSTRING(string_val,start_index,end_index)
```

Argument	Required?	Data Type	Description
<code>string_val</code>	Y	string	String literal to be applied to the function
<code>start_index</code>	Y	integer (non-negative)	Index value for the start character from the source column or value
<code>end_index</code>	Y	integer (non-negative)	Index value for the end character from the source column or value

For more information on syntax standards, see *Language Documentation Syntax Notes*.

string_val

String constant to be searched.

- Missing string values generate missing string results.
- String constants must be quoted (`'Hello, World'`).
- Multiple columns and wildcards are not supported.

Usage Notes:

Data Type	Required?	Example Value
-----------	-----------	---------------

String	Yes	'This is my string.'
--------	-----	----------------------

start_index

Index value of the character in the string to begin the substring match.

- The index of the first character of the string is 0.
- Value must be less than `end_index`.
- If this value is greater than the length of the string, a missing value is returned.

Usage Notes:

Data Type	Required?	Example Value
Integer (non-negative)	Yes	0

end_index

Index value of the character in the string that is one after the end the substring match.

- Value must be greater than `start_index`.
- If this value is greater than the length of the string, the end of the string is the end of match. If you know the maximum length of your data, you can use that value here.

Usage Notes:

Data Type	Required?	Example Value
Integer (non-negative)	Yes	5

Examples

Tip: For additional examples, see *Common Tasks*.

Example - Sectional Information in Zipcodes

Source:

A US zip code contains five digits with an optional Zip+4 extension consisting of four digits. Valid zip code values can be a mixture of these formats.

Within zip code values, each digit has significance:

- Digit 1: Zip code section
- Digits 2-3: Region within section
- Digits 4-5: area or town within region
- Digits 6-9: Optional Zip+4 identifier within area or town

Here is some example data:

LastName	ZipCode
Able	94101

Baker	23502-1122
Charlie	36845

Transform:

You are interested in the region and area or town identifiers within a zip code region. You can use the following transforms applied to the `ZipCode` column to extract this information:

```
derive type:single value:SUBSTRING(ZipCode,1,3)
```

```
derive type:single value:SUBSTRING(ZipCode,3,5)
```

- Since the string can be five or ten characters in length, you need to use the `SUBSTRING` function in the second transform, too. If the data is limited to five-digit zip codes, you could use the `RIGHT` function.

Results:

LastName	ZipCode	substring_ZipCode	substring_ZipCode2
Able	94101	41	01
Baker	23502-1122	35	02
Charlie	36845	68	45
